

The model is a tool, not the loop driver

request

waitFor

block

b-threads bid; an
arbiter picks

Behavioral runtime coordinates events — the model is
just one request `model.respond`

Model returns function calls as **data, not actions** →
inspected *before* dispatch

`useTrace` captures the full trajectory — the “**exhaust**”

An **autoresearch loop** uses that exhaust to evolve which
b-threads run next

**Neural proposes · symbolic disposes ·
the exhaust is the teacher.**
